## Accessibility features in video games

- subtitles
- selectable colorblindness-friendly color schemes
- ability to disable effects like screen shake, flicker, etc.
- remappable key bindings
- independent volume settings for dialogue, sound effects, music
- redundancy in information presentation
- others?

### **Discussion questions**

- Should every game be accessible to every potential player?
- How much responsibility for accessability should fall on features within games? (vs assistive technology used by the player to interact with the game?)
- Should we prefer strategies to make mainstream games accessible over games designed specifically to be accessible to a certain group? (For example, one-switch games or audio-only games.)
- I could find almost no products addressing videogame accessibility for players with cognitive impairments (with the exception of educational titles). What types of assistive technology and/or game design strategies would be helpful for this population?

- In research projects, reduction is often used as a strategy for making games accessible to users with motor impairments. This usually means reducing the complexity of gameplay or automating some aspects of gameplay. Is reduction a good/valid strategy for games accessibility?
- Is including an easy mode a valid strategy for games accessibility?
- Some computer games use programmatic strategies to block input that does not come from a physical mouse or keyboard. This is intended to prevent cheating, but it also prevents the use of many assistive technologies. Is this ethical?
